# Signed and Roman Edge Dominating Functions of Corona Product Graph of a Cycle with a Complete Graph 

J. ANITHA ${ }^{1}$, B. MAHESWARI ${ }^{2}$<br>${ }^{1}$ Department of Mathematics, S.D.M.S., Mahila College, Vijayawada, Andhra Pradesh, India<br>${ }^{2}$ Department of Applied Mathematics, Sri Padmavati Mahila Visvavidyalayam, Tirupati, Andhra Pradesh, India

#### Abstract

Graph Theory has been realized as one of the most useful branches of Mathematics of recent origin with wide applications to combinatorial problems and classical algebraic problems. Graph theory has applications in diverse areas such as social sciences, linguistics, physical sciences, communication engineering etc. The theory of domination in graphs is an emerging area of research in graph theory today. It has been studied extensively and finds applications to various branches of Science \& Technology. An introduction and an extensive overview on domination in graphs and related topics is surveyed and detailed in the two books by Haynes et al [13, 14]. Frucht and Harary [11] introduced a new product on two graphs G1 and G2, called corona product denoted by G18G2. The object is to construct a new and simple operation on two graphs G1 and G2 called their corona, with the property that the group of the new graph is in general isomorphic with the wreath product of the groups of G1 and of G2. In this paper, some results on minimal signed and Roman edge dominating functions of corona product graph of a cycle with a complete graph are presented.

Indexed Terms: Corona Product, Cycle, Complete graph, signed edge dominating function, Roman edge dominating function

## I. INTRODUCTION

Domination Theory has a wide range of applications to many fields like Engineering, Communication Networks, Social sciences, linguistics, physical sciences and many others. Allan, R.B. and Laskar, R.[1], Cockayne, E.J. and Hedetniemi, S.T. [7] have studied various domination parameters of graphs.

Products are often viewed as a convenient language with which one can describe structures, but they are increasingly being applied in more substantial ways. Every branch of mathematics employs some notion of product that enables the combination or decomposition of its elemental structures.

The concept of edge domination was introduced by Mitchell and Hedetniemi [18] and it is explored by many researchers. Arumugam and Velammal [6] have discussed the edge domination in graphs while the fractional edge domination in graphs is discussed in Arumugam and Jerry [5]. The complementary edge domination in graphs is studied by Kulli and Soner [17] while Jayaram [16] has studied the line dominating sets and obtained bounds for the line domination number. The bipartite graphs with equal edge domination number and maximum matching cardinality are characterized by Dutton and Klostermeyer [10] while Yannakakis and Gavril [20] have shown that edge dominating set problem is NPcomplete even when restricted to planar or bipartite graphs of maximum degree.

CORONA PRODUCT OF $C_{n}$ AND $K_{m}$
The corona product of a cycle $C_{n}$ with a complete graph $K_{m}$ is a graph obtained by taking one copy of a $n$ - vertex graph $C_{n}$ and $n$ copies of $K_{m}$ and then joining the $i^{\text {th }}$ vertex of $C_{n}$ to every vertex of $i^{\text {th }}$ copy of $K_{m}$. This graph is denoted by $C_{n} \odot K_{m}$.

The vertices of $C_{n}$ are denoted by $v_{1}, v_{2}, \ldots, v_{n}$. The edges in $C_{n}$ are denoted by $e_{1}, e_{2}, \ldots, e_{n}$ where $e_{i}$ is the edge joining the vertices $v_{i}$ and $v_{i+1}, i \neq n$. For $i=n, e_{n}$ is the edge joining the vertices $v_{n}$ and $v_{1}$.

The vertices in the $i^{\text {th }}$ copy of $K_{m}$ are denoted by $w_{i 1}, w_{i 2}, \ldots, w_{i m}$. The edges in the $i^{\text {th }}$ copy of $K_{m}$ are denoted by $l_{i j}, j=1,2, \ldots, \frac{m(m-1)}{2}$.

There are another type of edges in $G$ denoted by $h_{i j}, i=1,2, \ldots, n$ and $j=1,2, \ldots, m$ is the edge joining the vertex $v_{i}$ of $C_{n}$ to vertex $w_{i j}$ of $i^{\text {th }}$ copy of $K_{m}$. These edges which are in $G$ and related to the $i^{t h}$ copy of $K_{m}$ are denoted by $h_{i 1}, h_{i 2}, \ldots, h_{i m}$ and
these are adjacent to each other and incident with the vertex $v_{i}$ of $C_{n}$.

Some properties of corona product graph $G=C_{n} \odot K_{m}$ are studied by Anita [2] and some results on minimal edge dominating sets and functions of this graph are presented in [3]. Further minimal total edge dominating sets and functions of this graph are also studied by the authors [4].

## II. SIGNED EDGE DOMINATING FUNCTION

The concept of Signed dominating function was introduced by Dunbar et al., [9]. There is a variety of possible applications for this variation of domination. By assigning the values -1 or +1 to the vertices of a graph we can model such things as networks of positive and negative electrical charges, networks of positive and negative spins of electrons and networks of people or organizations in which global decisions can be made.

In this section, we prove some theorems on minimal signed edge dominating functions of the graph $G=$ $C_{n} \odot K_{m}$. Let us recall the definitions of signed edge dominating function and minimal signed edge dominating function of a graph $G(V, E)$.

Definition: Let $G(V, E)$ be a graph. A function $f$ : $E \rightarrow\{-1,1\}$ is called a signed edge dominating function (SEDF) of $G$ if

$$
f(\mathrm{~N}[e])=\sum_{e^{\prime} \in N[e]} f\left(e^{\prime}\right) \geq 1, \forall e \in E(G)
$$

A signed edge dominating function $f$ of $G$ is called a minimal signed edge dominating function (MSEDF) if for all $g<f, g$ is not a signed edge dominating function.

We need the following Theorem which is presented in [2].

Theorem 2.1: The adjacency of an edge $e$ in $G=$ $C_{n} \odot K_{m}$ is given by
$\operatorname{adj}(e)=\left\{\begin{array}{l}2 m+2, \text { if } e=e_{i} \in C_{n}, \\ 2 m-2, \text { if } e=l_{i j} \in i^{t h} \text { copy of } K_{m}, \\ 2 m, \text { if } e=h_{i j} \in G=C_{n} \odot K_{m} .\end{array}\right.$

Theorem 2.2: A function $f: E \rightarrow\{-1,1\}$ defined by
$f(e)=$
$\left\{-1\right.$, for $(m-1)$ edges $e=l_{i j}$ in each copy of $K_{m}$, (1, otherwise.
is a minimal signed edge dominating function of $G=C_{n} \odot K_{m}$.

Proof: Let $f$ be a function defined as in the hypothesis. By the definition of the function - 1 is assigned to $(m-1)$ edges $l_{i j}$ in each copy of $K_{m}$ in $G$ and 1 is signed to the remaining edges of $G$. The summation value taken over $\mathrm{N}[e]$ of $e \in E$ is as follows.

Case 1: Let $e_{i} \in C_{n}$, be such that $\operatorname{adj}\left(e_{i}\right)=2 m+2$ in $G$.

Then $\mathrm{N}\left[e_{i}\right]$ contains three edges of $C_{n}$ and $2 m$ edges which are drawn from the vertices $v_{i}$ and $v_{i+1}$ respectively to the $m$ vertices of $i^{t h}$ and $(i+1)^{t h}$ copies of $K_{m}$ and their functional value is 1 .

$$
\begin{aligned}
& \text { Therefore } \sum_{e \in N\left[e_{i}\right]} f(e) \\
& =1+1+1+\underbrace{[1+1+\cdots+1]}_{2 m \text {-times }} \\
& =2 m+3 .
\end{aligned}
$$

Case 2: Let $l_{i k} \in i^{t h}$ copy of $K_{m}$. By the definition of $f,(m-1)$ edges $l_{i j}$ are assigned -1 and the remaining edges are assigned 1 .

By Theorem 2.1, $\operatorname{adj}\left(l_{i k}\right)=2 m-2$. That is the edge $l_{i k}$ is adjacent to $(2 m-4)$ edges $l_{i j}, j \neq k$ and two edges $h_{i j}$. Here $f\left(h_{i j}\right)=1$.

$$
\text { So } \begin{aligned}
\sum_{e \in N\left[l_{i k}\right]} f(e)= & {[(m-1)(-1)+(m-2)(1)] } \\
& +1+1=1
\end{aligned}
$$

Now for all other possibilities of functional values of $l_{i j}$ that are adjacent to $l_{i k}, k=1,2, \ldots, m$, we could see that
$\sum_{e \in N\left[l_{i j}\right]} f(e)>1$.

Case 3: Let $h_{i j} \in C_{n} \odot K_{m}$ be such that $\operatorname{adj}\left(h_{i j}\right)=$ $2 m$ in $G$.

Then $\mathrm{N}\left[h_{i j}\right]$ contains two edges of $C_{n}, m$ edges $h_{i j}$ and $(m-1)$ edges $l_{i j}$ in $K_{m}$.

Suppose $f\left(l_{i j}\right)=-1$ for all $(m-1)$ edges $l_{i j}$ that are adjacent to $h_{i j}$. Then

$$
\begin{aligned}
\sum_{e \in N\left[h_{i j}\right]} f(e)=1 & +1+[(m-1)(-1)+(m)(1)] \\
& =3
\end{aligned}
$$

Suppose $f\left(l_{i j}\right)=1$ for all $(m-1)$ edges $l_{i j}$ that are adjacent to $h_{i j}$. Then

$$
\begin{aligned}
\sum_{e \in N\left[h_{i j}\right]} f(e)=1 & +1+[(m-1)(1)+(m)(1)] \\
& =2 m+1
\end{aligned}
$$

Thus as in Case 2 for all other possibilities of functional values for the $(m-1)$ edges that are adjacent to $h_{i j}$ we could see that
$\sum_{e \in N\left[h_{i j}\right]} f(e)>1$.
Therefore, for all possibilities we get
$\sum_{e \in E(G)} f(e) \geq 1$, for all $e \in E(G)$.

Hence $f$ is a signed edge dominating function.
We now check for the minimality of $f$.
Define a function $g: E \rightarrow\{-1,1\}$ by
g(e)
$=\left\{\begin{array}{l}-1, \text { for one edge } h_{i k}, \\ -1, \text { for }(m-1) \text { edges } l_{i j} \text { in each copy of } K_{m}, \\ 1, \text { otherwise. }\end{array}\right.$
Since strict inequality holds at $h_{i k}$ it follows that $g<$ $f$.

Case (i): Let $e_{i} \in C_{n}$ be such that $\operatorname{adj}\left(e_{i}\right)=2 m+2$ in $G$.

Sub Case 1: Let $h_{i k} \in N\left[e_{i}\right]$. Then

$$
\begin{gathered}
\sum_{e \in N\left[e_{i}\right]} g(e)=-1+1+1+\underbrace{[1+1+\cdots+1]}_{2 m \text {-times }} \\
=2 m+1 .
\end{gathered}
$$

Sub Case 2: Let $h_{i k} \notin N\left[e_{i}\right]$. Then

$$
\begin{gathered}
\sum_{e \in N\left[e_{i}\right]} g(e)=1+1+1+\underbrace{[1+1+\cdots+1]}_{2 m-\text { times }} \\
=2 m+3 .
\end{gathered}
$$

Case (ii): Let $l_{i k} \in i^{t h}$ copy of $K_{m}$. Then $\operatorname{adj}\left(l_{i k}\right)=$ $2 m-2$ in $G$.

Sub Case 1: Let $h_{i k} \in N\left[l_{i k}\right]$. Then

$$
\begin{aligned}
\sum_{e \in N\left[l_{i k}\right]} g(e)= & {[(m-1)(-1)+(m-1)(1)] } \\
& +(-1)=-1
\end{aligned}
$$

Sub Case 2: Let $h_{i k} \notin N\left[l_{i k}\right]$. Then

$$
\begin{aligned}
\sum_{e \in N\left[l_{i k}\right]} g(e)= & {[(m-1)(-1)+(m-1)(1)]+1 } \\
& =1
\end{aligned}
$$

Now for all other possibilities of functional values of $l_{i j}$ that are adjacent to $l_{i k}$ we could see that
$\sum_{e \in N\left[l_{i j}\right]} g(e)>1$.

Case (iii): Let $h_{i j} \in C_{n} \odot K_{m}$ be such that $\operatorname{adj}\left(h_{i j}\right)=2 m$ in $G$.

Sub case 1: Let $h_{i k} \in N\left[h_{i j}\right]$.
Suppose $g\left(l_{i j}\right)=-1$ for all $(m-1)$ edges $l_{i j}$ that are adjacent to $h_{i j}$. Then

$$
\begin{aligned}
\sum_{e \in N\left[h_{i j}\right]} g(e)=1 & +1 \\
& +[(m-1)(-1)+(m-1)(1)] \\
& +(-1)=1 .
\end{aligned}
$$

Suppose $\boldsymbol{g}\left(\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}}\right)=\mathbf{1}$ for all $(\boldsymbol{m}-\mathbf{1})$ edges $\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}}$ that are adjacent to $\boldsymbol{h}_{\boldsymbol{i} \boldsymbol{j}}$. Then

$$
\begin{aligned}
\sum_{e \in N\left[h_{i j}\right]} g(e)=1 & +1 \\
& +[(m-1)(1)+(m-1)(1)] \\
& +(-1)=2 m-1
\end{aligned}
$$

Sub Case 2: Let $\boldsymbol{h}_{\boldsymbol{i k}} \notin \boldsymbol{N}\left[\boldsymbol{h}_{\boldsymbol{i} \boldsymbol{j}}\right]$.

Suppose $\boldsymbol{g}\left(\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}}\right)=\mathbf{- 1}$ for all $(\boldsymbol{m}-\mathbf{1})$ edges $\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}}$ that are adjacent to $\boldsymbol{h}_{\boldsymbol{i} \boldsymbol{j}}$. Then

$$
\begin{aligned}
\sum_{e \in N\left[h_{i j}\right]} g(e)=1 & +1+[(m-1)(-1)+(m)(1)] \\
= & 3
\end{aligned}
$$

Suppose $\boldsymbol{g}\left(\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}}\right)=\mathbf{1}$ for all $(\boldsymbol{m}-\mathbf{1})$ edges $\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}}$ that are adjacent to $\boldsymbol{h}_{\boldsymbol{i} \boldsymbol{j}}$. Then

$$
\begin{aligned}
\sum_{e \in N\left[h_{i j}\right]} g(e)=1 & +1+[(m-1)(1)+(m)(1)] \\
= & 2 m+1
\end{aligned}
$$

We see that
$\sum_{e \epsilon E[G]} g(e)<1$, for some $e \in E(G)$.
So $\boldsymbol{g}$ is not an edge dominating function. Since $\boldsymbol{g}$ is defined arbitrarily, it follows that there exists no $\boldsymbol{g}<$ $\boldsymbol{f}$ such that $\boldsymbol{g}$ is an edge dominating function.

Thus $\boldsymbol{f}$ is a minimal signed edge dominating function.

## III. ROMAN EDGE DOMINATING FUNCTION

The Roman dominating function of a graph $\boldsymbol{G}$ was defined by Cockayne et al. [8]. The definition of a Roman dominating function was motivated by an article in Scientific American by Ian Stewart [15] entitled "Defend the Roman Empire!", Henning et.al [12] and suggested even earlier by ReVelle [19].

In this section first we recall the definitions of Roman edge dominating function of a graph. Later results on minimal Roman edge dominating functions of $\boldsymbol{G}=$ $\boldsymbol{C}_{\boldsymbol{n}} \odot \boldsymbol{K}_{\boldsymbol{m}}$ are discussed.

Definition: Let $\boldsymbol{G}(\boldsymbol{V}, \boldsymbol{E})$ be a graph. A function $\boldsymbol{f}$ : $\boldsymbol{E} \rightarrow\{\mathbf{0}, \mathbf{1}, \mathbf{2}\}$ is called a Roman edge dominating function (REDF) of $\boldsymbol{G}$ if

$$
\begin{aligned}
& f(\mathbf{N}[e]) \\
& =\sum_{e^{\prime} \in \mathbf{N}[e]}^{\in E(G)} f\left(e^{\prime}\right) \geq 1, \forall e
\end{aligned}
$$

and satisfying the condition that every edge $\boldsymbol{e}$ for which $\boldsymbol{f}(\boldsymbol{e})=\mathbf{0}$ is adjacent to at least one edge $\boldsymbol{e}^{\prime}$ for which $\boldsymbol{f}\left(\boldsymbol{e}^{\prime}\right)=\mathbf{2}$.

A Roman edge dominating function $\boldsymbol{f}$ of $\boldsymbol{G}$ is called a minimal Roman edge dominating function (MREDF) if for all $\boldsymbol{g}<\boldsymbol{f}, \boldsymbol{g}$ is not a Roman edge dominating function.

Theorem 3.1: A function $\boldsymbol{f}: \boldsymbol{E} \rightarrow\{\mathbf{0}, \mathbf{1}, 2\}$ defined by
$f(e)=$
$\left\{2\right.$, for $(m-1)$ edges $h_{i j}$ in $C_{n} \odot K_{m}$, 0, otherwise.
is a minimal Roman edge dominating function of $\boldsymbol{G}=$ $\boldsymbol{C}_{\boldsymbol{n}} \odot \boldsymbol{K}_{\boldsymbol{m}}$.

Proof: Let $\boldsymbol{f}$ be a function defined as in the hypothesis.
Case 1: Let $\boldsymbol{e}_{\boldsymbol{i}} \in \boldsymbol{C}_{\boldsymbol{n}}$ be such that $\boldsymbol{\operatorname { a d j }}\left(\boldsymbol{e}_{\boldsymbol{i}}\right)=\mathbf{2 m}+\mathbf{2}$ in $\boldsymbol{G}$.

Then $\boldsymbol{N}\left[\boldsymbol{e}_{\boldsymbol{i}}\right]$ contains $\boldsymbol{m}$ edges $\boldsymbol{h}_{\boldsymbol{i 1}}, \boldsymbol{h}_{\boldsymbol{i 2}}, \ldots, \boldsymbol{h}_{\boldsymbol{i m}}$ of $\boldsymbol{G}$ ,again $\boldsymbol{m}$ edges $\boldsymbol{h}_{(i+1) 1}, \boldsymbol{h}_{(i+1) 2}, \ldots, \boldsymbol{h}_{(i+1) \boldsymbol{m}}$ of $\boldsymbol{G}$ and three edges of $\boldsymbol{C}_{\boldsymbol{n}}$.

$$
\text { So } \begin{aligned}
\sum_{e \in N\left[e_{i}\right]} f(e)= & 0+0+0+\underbrace{[2+2+\cdots+2]}_{(2 m-2) \text { times }}+0 \\
& +0=4 m-4 .
\end{aligned}
$$

Case 2: Let $\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}} \in \boldsymbol{i}^{\boldsymbol{t h}}$ copy of $\boldsymbol{K}_{\boldsymbol{m}}$. Then $\boldsymbol{a d j}\left(\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}}\right)=$ $2 m-2$ in G.

Then $\boldsymbol{N}\left[\boldsymbol{l}_{\boldsymbol{i j}}\right]$ contains $(\mathbf{2 m}-\mathbf{3})$ edges of $\boldsymbol{K}_{\boldsymbol{m}}$ and two edges $\boldsymbol{h}_{\boldsymbol{i j}}$ of $\boldsymbol{G}$. Then

$$
\begin{gathered}
\sum_{e \in N\left[l_{i j}\right]} f(e)=\underbrace{[0+0+\cdots+0]}_{(2 m-3)-\text { times }}+2+2 \\
=4
\end{gathered}
$$

or

$$
\sum_{e \in N\left[l_{i j}\right]} f(e)=\underbrace{[0+0+\cdots+0]}_{(2 m-3)-\text { times }}+2+0
$$

$$
=2
$$

Case 3: Let $\boldsymbol{h}_{\boldsymbol{i} \boldsymbol{j}} \in \boldsymbol{C}_{\boldsymbol{n}} \odot \boldsymbol{K}_{\boldsymbol{m}}$ be such that $\boldsymbol{a d j}\left(\boldsymbol{h}_{\boldsymbol{i} \boldsymbol{j}}\right)=$ $2 \boldsymbol{m}$ in $\boldsymbol{G}$.

$$
\text { Then } \begin{aligned}
\sum_{e \in N\left[h_{i j}\right]} f(e) & \\
& =0+0 \\
& +[(m-1) 2+(m-1) 0]+0 \\
& =2 m-2
\end{aligned}
$$

Therefore for all possibilities, we get
$\sum_{e \in E[G]} f(e)>1$.
Let $\boldsymbol{e}$ be an edge of $\boldsymbol{G}$ such that $\boldsymbol{f}(\boldsymbol{e})=\mathbf{0}$ and $\boldsymbol{e}^{\boldsymbol{\prime}}$ be another edge of G such that $\boldsymbol{e}^{\prime} \neq \boldsymbol{e}$ and $\boldsymbol{f}\left(\boldsymbol{e}^{\prime}\right)=\mathbf{2}$. Then we show that $\boldsymbol{e}$ and $\boldsymbol{e}^{\prime}$ are adjacent.

Now $\boldsymbol{f}(\boldsymbol{e})=\mathbf{0}$ implies $\boldsymbol{e}=\boldsymbol{e}_{\boldsymbol{i}} \in \boldsymbol{C}_{\boldsymbol{n}}$ for some $\boldsymbol{i}$, or $e=\boldsymbol{l}_{\boldsymbol{i j}}$, for some $\boldsymbol{i}=1,2, \ldots, n$ and $\boldsymbol{j}=1,2, \ldots, m$.

Now $\boldsymbol{f}\left(\boldsymbol{e}^{\prime}\right)=\mathbf{2}$ implies $\boldsymbol{e}^{\prime}=h_{i j}, \boldsymbol{i}=\mathbf{1}, \mathbf{2}, \ldots, \boldsymbol{n}$ and $j=1,2, \ldots,(m-1)$.

Suppose $\boldsymbol{e}=\boldsymbol{e}_{\boldsymbol{i}} \in \boldsymbol{C}_{\boldsymbol{n}}$. Then obviously $\boldsymbol{e}_{\boldsymbol{i}}$ and $\boldsymbol{h}_{\boldsymbol{i} \boldsymbol{j}}$ are adjacent. That is $\boldsymbol{e}$ and $\boldsymbol{e}^{\prime}$ are adjacent.

Suppose $\boldsymbol{e}=\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}}$ for some $\boldsymbol{i}$ and j . Then $\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}}$ and $\boldsymbol{h}_{\boldsymbol{i} \boldsymbol{j}}$ are adjacent. That is $\boldsymbol{e}$ and $\boldsymbol{e}^{\prime}$ are adjacent.

This implies that $\boldsymbol{f}$ is a Roman edge dominating function.

Now we
check for the minimality of $\boldsymbol{f}$. Define a function $\boldsymbol{g}: \boldsymbol{E} \rightarrow\{\mathbf{0}, \mathbf{1}, \mathbf{2}\}$ by $\mathbf{g}(\mathbf{e})=$ (1,for one edge $h_{i k}$ in $C_{n} \odot K_{m}$,
$\left\{\begin{array}{l}2, \text { for }(m-2) \text { edges } h_{i j} \text { in } C_{n} \odot K_{m}, \mathbf{j} \neq \mathbf{k}, \\ 0, \text { otherwise. }\end{array}\right.$

Since strict inequality holds at an edge $\boldsymbol{h}_{\boldsymbol{i} \boldsymbol{k}}$, it follows that $\boldsymbol{g}<\boldsymbol{f}$.

Case (i): Let $\boldsymbol{e}_{\boldsymbol{i}} \in \boldsymbol{C}_{\boldsymbol{n}}$ be such that $\boldsymbol{a d j}\left(\boldsymbol{e}_{\boldsymbol{i}}\right)=\mathbf{2 m}+$ 2
in
G. Sub Case 1: Let $\boldsymbol{h}_{\boldsymbol{i k}} \in \boldsymbol{N}\left[\boldsymbol{e}_{\boldsymbol{i}}\right]$. Then

$$
\begin{aligned}
& \sum_{e \in N\left[e_{i}\right]} g(e)=0+0+0 \\
&+\underbrace{[2+2+\cdots+2]}_{(2 m-3) t i m e s}+1 \\
&+0+0=4 m-5 .
\end{aligned}
$$

Sub Case 2: Let $\boldsymbol{h}_{\boldsymbol{i} \boldsymbol{k}} \notin \boldsymbol{N}\left[\boldsymbol{e}_{\boldsymbol{i}}\right]$. Then

$$
\begin{aligned}
\sum_{e \in N\left[e_{i}\right]} g(e)=0 & +0+0+\underbrace{[2+2+\cdots+2]}_{(2 m-2) \text { times }}+0 \\
& +0=4 m-4 .
\end{aligned}
$$

Case (ii): Let $\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}} \in \boldsymbol{i}^{\boldsymbol{t h}}$ copy of $\boldsymbol{K}_{\boldsymbol{m}}$. Then $\boldsymbol{a d j}\left(\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}}\right)=$ $2 \boldsymbol{m}-2$ in $\boldsymbol{G}$.

Sub Case 1: Let $\boldsymbol{h}_{\boldsymbol{i} \boldsymbol{k}} \in \boldsymbol{N}\left[\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}}\right]$. Then

$$
\begin{aligned}
& \sum_{e \in N\left[l_{i j}\right]} g(e)=\underbrace{[0+0+\cdots+0]}_{(2 m-3) t i m e s}+1+2 \\
& =
\end{aligned}
$$

or

$$
\begin{aligned}
& \quad \sum_{e \in N\left[l_{i j}\right]} g(e)=\underbrace{[0+0+\cdots+0]}_{(2 m-3) \text { times }}+1+0 \\
& =
\end{aligned}
$$

Sub Case 2: Let $\boldsymbol{h}_{\boldsymbol{i k}} \notin \boldsymbol{N}\left[\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}}\right]$. Then

$$
\begin{aligned}
& \sum_{e \in N\left[l_{i j}\right]} g(e)=\underbrace{[0+0+\cdots+0]}_{(2 m-3) \text { times }}+2+2 \\
& =4,
\end{aligned}
$$

or

$$
\begin{aligned}
& \sum_{e \in N\left[l_{i j}\right]} g(e)=\underbrace{[0+0+\cdots+0]}_{(2 m-3) \text { times }}+2+0 \\
= & 2 .
\end{aligned}
$$

Case (iii): Let $\boldsymbol{h}_{\boldsymbol{i j}} \in \boldsymbol{C}_{\boldsymbol{n}} \odot \boldsymbol{K}_{\boldsymbol{m}}$ be such that $\operatorname{adj}\left(h_{i j}\right)=\mathbf{2 m}$ in $\boldsymbol{G}$.

Sub Case 1: Let $\boldsymbol{h}_{\boldsymbol{i} \boldsymbol{k}} \in \boldsymbol{N}\left[\boldsymbol{h}_{\boldsymbol{i} \boldsymbol{j}}\right]$. Then

$$
\begin{aligned}
\sum_{e \epsilon N\left[h_{i j}\right]} g(e)=0 & +0+[(m-2) 2+m(0)]+1 \\
& =2 m-3 .
\end{aligned}
$$

Sub Case 2: Let $\boldsymbol{h}_{\boldsymbol{i} \boldsymbol{k}} \notin \boldsymbol{N}\left[\boldsymbol{h}_{\boldsymbol{i} \boldsymbol{j}}\right]$.

$$
\begin{aligned}
\sum_{e \epsilon N\left[h_{i j}\right]} g(e)=0 & +0+[(m-1) 2+m(0)] \\
& =2 m-2
\end{aligned}
$$

Hence for all possibilities, we get
$\sum_{e \epsilon E(G)} g(e)>1$, for all $e$
$\in \boldsymbol{E}(\boldsymbol{G})$.
i.e. $\boldsymbol{g}$ is an edge dominating function. But $\boldsymbol{g}$ is not a Roman edge dominating function, since the REDF definition fails in the $\boldsymbol{i}^{\boldsymbol{t h}}$ copy of $\boldsymbol{K}_{\boldsymbol{m}}$ in $\boldsymbol{G}$.

Let the edge $\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}} \in \boldsymbol{i}^{\boldsymbol{t h}}$ copy of $\boldsymbol{K}_{\boldsymbol{m}}$. Then $\boldsymbol{g}\left(\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}}\right)=$ $\mathbf{0}$. We know that every edge $\boldsymbol{l}_{\boldsymbol{i} \boldsymbol{j}}$ in $\boldsymbol{K}_{\boldsymbol{m}}$ is adjacent to two edges $h_{i j}, j=1,2, \ldots, m$.

The condition of Roman dominating function fails for the edge $l_{i j}$ which is adjacent to $h_{i k}$ and $h_{i j}$ where $g\left(h_{i k}\right)=1$ and $g\left(h_{i j}\right)=0$.

Thus $f$ is a minimal Roman edge dominating function.
