#### Abstract

As the economy grows and real income of household increases, vehicle population surges up, contributing to traffic congestion, particularly within cities. Given the critical importance of productivity on the Gross Domestic Product (GDP) growth, it is economically worthwhile, and of policy importance to recognize causes of congestion and their harmful effect. This study investigates the causes of traffic congestion, focusing on a selected road link (KaruKeffi, Mararaba in Nasarawa State, Nigeria). Physical manual traffic survey was used to gather the data and Descriptive Statistics employed to analyze the data. The average traffic volume on the road was observed to be 4346veh/hr as compared to 2595 veh/hr (Model Road State (MRS) HCM 2000), signifying almost $170 \%$ increase. The average travel speed found to be 11kmph and the FFS of 45 kmph , giving level of service (LOS) classification of $F$ (signifying breakdown in the flow of traffic). The findings and recommendations herein will help to curb possible traffic congestion and ensure proper traffic management and control consistent with specifications for the smart city.

Indexed Terms- Traffic Congestion, Smart City, Level of Service, Traffic Volume, Traffic Survey.

## I. INTRODUCTION

The department of Transport U.S. (2005), Defined traffic congestion as essentially a relative phenomenon that is linked with the different road way system performance that road users expect and how the system actually performs. Furthermore, European conference of ministers of transport (ECMT) (1999) Defined congestion as long queues of vehicles which are constantly stopping and starting passengers cannot move in a desirable manner under the serious
conditions. This is a condition of traffic delays whereby traffic flow is slowed below reasonable speeds because the number of vehicles to use exceeds the design capacity of the traffic to handle it.

Traffic Congestion continues to remain major problem in most cities all over the world, most especially developing regions resulting in massive delays, monetary losses, fuel wastage, and accidents that sometimes result into death. Due to poorly planned road networks, and poor traffic management, that results into elongated traffic congestion.

Road transport (land) is major dominant mode of transport in Nigeria, with over $90 \%$ of (Users) passengers and freight traffic. Latest report from the Nigeria Bureau of statistics NBA, (2023) has estimated, the total vehicle population in Nigeria is about 11.8 million, with commercial vehicle holding about $58.08 \%$; private are 4,739,939 ( $40.67 \%$ ) while diplomatic vehicles

Karu Local Government Area of Nasarawa State is located between latitudes $8^{\circ} 5^{\prime} \mathrm{N}$ and $10^{\circ} 42^{\prime} \mathrm{N}$ and longitudes $9^{\circ} 25^{\prime} \mathrm{E}$ and $7^{\circ} 54^{\prime} \mathrm{E}$. Karu is an unplanned area covering a spatial extent of about 800sqkm. It extends from the eastern boundary of the Federal Capital Territory Abuja (Old Nyanya) to Gora about 15 kilometers to Keffi. The area has an estimated population of 10,000 in 1991, and is believed to have grown rapidly to an estimated population of 50,000 and 130,000 by 2001 and 2010 respectively; due to continuous migration of people from other parts of the country to this area. Its current population is estimated at 205, 477.

Nasarawa as whole is sometimes faced with the challenge of traffic congestion. Congestion prevents us from moving freely and it slows and otherwise
disrupts the conduct of business within urban areas. However, it is important to note that unfettered movement is not the primary benefit we derive from living in urban areas.

Nasarawa provides access to a wide range of activities, people, services, goods, markets, opportunities, ideas and networks. These benefits can be delivered either through speed or through greater proximity. Congestion may affect travel speed but, in some circumstances such as dense urban cores, congestion may both be expected and, to some degree accepted. In these cases, the Nasarawa has come to accept a degree of congestion and continue to get along relatively well as long as overall accessibility is high. The research helps to understand the magnitude of congestion along Keffi-Karu(Mararaba) road in Nasarawa State thus coming up with possible and valid management control measures. It provides valid traffic control measures so as to reduce travel time and other effects of congestion. This would increase gross domestic product that would boost the economy since there would be reduced delays, comfortability in transport systems and efficiency. It will have an important implication for policymakers to understand that since congestion takes place on the roads, it is not only a traffic engineering problem, but sustainability issue in general.

## The MAIN OBJECTIVEs incuced the following

- To carry out traffic count
- To determine traffic stream characteristics
- To determine level of service
- To find out the traffic flow rate and peak hour factors
- To determine the capacity of road section
- To investigate the magnitude of traffic congestion along Keffi-Karu(Mararaba) road in Nasarawa State.
- To provide mitigation measures to traffic congestion in light of sustainability approach.

## II. METHODOLOGY

The methodology covered the research design, sources of data, study area, method of data collection, data collection instrument, and procedures which were adopted in order to achieve the objectives.

### 2.1 SOURCES OF DATA

Basically, the information needed for this project was obtained from the following sources .The data was obtained from both primary and secondary sources Primary sources include; direct acquisition of information by conducting traffic counting, This helped to gather exact information to assess the magnitude of congestion Secondary sources include; using records from journals, libraries, magazines or using internet from visiting websites, Research from lecture notes and handbooks

### 2.2 DATA COLLECTION

## METHOD OF DATA COLLECTION

Traffic assessment was conducted to provide traffic flow data, this included traffic counting and projection.
It also helped to determine traffic stream parameters that enabled assessing the magnitude of traffic congestion along Keffi-Karu(Mararaba) Road.
It was carried out manually through daily traffic counting and recording traffic volumes per 15 minutes (AADT Veh/15min) Using A Test vehicle to determine free flow speed (high way capacity manual)

## PROCEDURES OF DATA COLLECTION

## TRAVEL SPEED

For determining the average speed of the vehicles the License Plate method is used, the observers were positioned in the two stations. In this method the observer is required to take the last four digits of some of the vehicles passing the road at the first station, as well as the time of passing this station is also recorded using stopwatch. The time of arrival to the second station is also recorded with the last four digits of the vehicle. It's not possible to do this process for all vehicles, only some vehicles can be recorded in both stations. The difference between two recorded times is the travel time of this vehicle. The average of travel time can be calculated as a mean of observed travel time of all vehicles, equation below was used for determining the average travel speed.

$$
S=\frac{n L}{\sum_{i=1}^{n} t_{i}}=\frac{L}{\frac{1}{n} \sum_{i=1}^{n} t_{i}}=\frac{L}{t_{a}}
$$

Where: S - The average travel speed in ( kph ), n is number of matched plates,

L - The length of the test section (m), in this case $\mathrm{L}=$ $100 \mathrm{~m}, \mathrm{t}$ - The recorded Time in (sec.).

## TRAVEL VOLUME

The rate of flow was measured throughout one week to take in consideration all different days of the week including the weekend from 06:00 to 06:00. Late night hours were neglected because traffic flow is reduced too much. The Counting intervals were 15 minutes.

## DENSITY

Density, k
Density was calculated from dividing a number of vehicles occupying a given length of the selected section of the road by length and is generally expressed as vehicles per km .
Density, $\mathrm{k}=\frac{n}{x}$
Where: k - Density, n - Number of vehicles per the given length,
x - Length of the selected section.

## FLOW RATE

This represents the number of vehicles that were observed passed a point during a time interval less one hour but expressed as an equivalent hourly rate.
Flow rate is the number of vehicles observed in a sub hourly period, divided by the time (in hours) of the observation since vehicles were observed in 15 minutes interval, thus
Flow rate $=\frac{\text { number of vehicle }}{0.25}$

## PEAK HOUR FACTOR

Peak flow rates and hourly volumes produce the peak hour factor (PHF), the ratio of total hourly volume to the peak flow rate (within the hour)
$\mathrm{PHF}=\frac{V}{4 \times V 15}$

Where:
PHF - Peak Hour Factor
V - Hourly volume (veh/hr)
V15 - volume during the peak 15 min of the peak hour (veh/15min)

## CAPACITY

Design capacity was obtained from the AASHTO pavement design manual However, possible capacity
or the capacity of the road based on the existing conditions was obtained by guidelines of HCM 2010

## FREE FLOW SPEED

Free flow Speed (FFS) is the average speed of a vehicle in a specific road, it was observed during very low traffic volume conditions or late night hours while drivers were not constrained by other vehicles or by traffic signals, FFS is measured using test car.

In this project, the FFS was obtained by marking runs with a test car during periods of late night hours. The FFS can be determined as the average of several speed reading of the car in different five nights according to the equation below

$$
F F S=\sum_{i=1}^{n} s_{i} / n
$$

Where:
FFS - The free flow speed (Kph),
n - number of samples in this case is 5 , and
S - The vehicle speed reading in each time (Kph)

## LEVEL OF SERVICE

Level of service (LOS) is a measure used to determine the effectiveness of elements of transportation infrastructure. LOS is most commonly used to analyze highways by categorizing traffic flow with corresponding safe driving conditions. According to Highway Capacity Manual (HCM) and AASHTO Geometric Design of Highways and Streets, the levels of service for any highway or street is ranked using letters A through F, with A being the best and F being the worst. The LOS was determined based on FFS and average travel speed

## III. RESULTS AND DISCUSSIONS

### 3.1 TRAFFIC VOLUME

Figure 1: The Pictorial View of The Traffic Flow At The Point Of Counting

The rate of flow was measured throughout one week to take into consideration all different days of the week including the weekend from 06:00 to 20:00. Late night hours were neglected because traffic flow is reduced too much. The Counting intervals were 15 minutes (HCM 2000). The table below shows results for hourly volumes of the week.

Table 1: Results for hourly volumes of the week.

| TIME (HRS) | TRAFFIC <br> $($ VEH/HR $)$ |
| :--- | :--- |
| $06: 00-07: 00$ | 1918 |
| $07: 00-08: 00$ | 2199 |
| $08: 00-09: 00$ | 1917 |
| $09: 00-10: 00$ | 2628 |
| $10: 00-11: 00$ | 3132 |
| $11: 00-12: 00$ | 3149 |
| $12: 00-13: 00$ | 2784 |
| $13: 00-14: 00$ | 2592 |
| $14: 00-15: 00$ | 2423 |
| $15: 00-16: 00$ | 2607 |
| $16: 00-17: 00$ | 2669 |
| $17: 00-18: 00$ | 2640 |
| $18: 00-19: 00$ | 2595 |
| $19: 00-20: 00$ | 2164 |

## - Passenger Car Equivalent

Passenger Car Equivalent (PCE) is a metric used to assess traffic-flow rate on highways. A Passenger Car Equivalent is the impact that a mode of transport has on traffic variables such as speed or volume of traffic if compared to a single car. The equivalent values for each kind of vehicles are shown in table below

Table 2: Passenger Car Equivalent
Passenger car (including private cars, taxi, and
pickups) 1
Bus, tractor, truck 3.5
Motorcycle 0.5
Bicycle 0.2
Horse-drawn vehicles 4

In this study, most of the vehicles were private cars, taxies, pickups, buses, and tractors. Some Motorcycles and Bicycles were not recorded because of their little effect and horse-drawn vehicles did not exist. We directly multiplied the number of vehicles by their
equivalent values to get the PCE/ 15 mins , and then PCE/h.

Figure 1: The traffic flow graph shown in the graph above

Every day two peak hours occur one at 11:00 and the second one at 16:00. The noticeable thing here is that, peak hours occur at the same time in both directions. The first rush hour is occurring at the beginning of the working day which is normal in all routes around the city. The second rush hour occurs on evenings when people are returning back to their homes. Another cause of the evening rush hour is a parallel parking, and also because of access roads.

The most significant rush hours are seen at 11:00 and 16:00 .this is due to the people going to and returning back from work, Market, and residential areas of Kuru and FCT

### 3.2 FLOW RATE

Flow rate is the number of vehicles observed in a sub hourly period, divided by the time (in hours) of the observation since vehicles were observed in 15 minutes interval ( HCM 2000), thus
Flow rate $=\frac{\text { number of vehicles }}{0.25}$

Traffic volume in PCEs is 4346

### 3.3 PEAK HOUR FACTOR

Peak flow rates and hourly volumes produce the peak hour factor (PHF), the ratio of total hourly volume to the peak flow rate (within the hour),(HCM 2000)
PHF $=\frac{V}{4 \times V_{15}}$

$$
\begin{aligned}
\text { PHF }= & \frac{3149}{4 \times 845} \\
& =0.93
\end{aligned}
$$

According to HCM (2000), PHFs in urban generally range between 0.8 to 0.98 . Lower values signify greater variability of flow within the subject hour and high values signify less flow variation .PHFs over 0.95 are often indicative of high traffic volumes sometimes with capacity constraints during the peak hour

### 3.4 CAPACITY

Capacity $=$ hourly capacity
Capacity factor in \%
Where:
Hourly Capacity = hourly capacity in PCE/hr by MRS Capacity Factor\% = proportion of daily traffic in the peak periods (MRS )
Capacity $=2575$ X 100

$$
\begin{aligned}
& 12.5 \\
= & 20,600
\end{aligned}
$$

### 3.5 VOLUME CAPACITY RATIO, (VCR)

VCR is calculated using the volume and capacity calculations
The VCR is a measure of the level of congestion on a road given the traffic volume and road capacity. When the VCR reaches 1, this indicates that the road is operating at $100 \%$ capacity.

The maximum VCR in CBA6 is 1.25 .

| $=4346$ |
| ---: |
| 20,600 <br> VCR <br> $=$ 0.2 |

3.6 TRAVEL SPEED

| LICENSE | LENGTH (M) | AV. <br> TRAVEL <br> TIME(S) |
| :--- | :--- | :--- |
| CLASS A | 100 | 15 |
| CLASS B | 100 | 30 |
| CLASS C | 100 | 40 |
| CLASS D | 100 | 45 |
|  | AVERAGE | 33 |

Travel speed $=0.1$

$$
\begin{aligned}
& (0.009) \\
& \quad=11 \mathrm{kph}
\end{aligned}
$$

NOTE:
Class A - Motor cycle
Class B - Motor vehicle of less than 3 tonnes gross weight, other than motor cycle, buses, taxi, stage carriage, or omnibus
Class C - Motor vehicle of less than 3 tonnes gross weight, other than motor cycle
Class D - motor vehicle other than motor cycle, taxi, stage carriage, an articulated vehicle or vehicle drawing a trailer

### 3.7 FREE FLOW SPEED

In this project, the FFS was obtained by marking runs with a test car during periods of late night hours. The FFS was determined as the average of several speed reading of the car in different five nights
$\mathrm{FFS}=\sum_{i-1}^{n} s_{i} / n$

Table 3: Table showing FFS

| DAY | FFS(kph) |
| :--- | :--- |
| Monday | 50 |
| Tuesday | 47 |
| Wednesday | 43 |
| Thursday | 45 |
| Friday | 40 |
| Average | 45 |

### 3.8 LEVEL OF SERVICE

According to Highway Capacity Manual (HCM) and AASHTO Geometric Design of Highways and Streets, the levels of service for any highway or street is ranked using letters A through F, with A being the best and F being the worst. The LOS was determined based on FFS and average travel speed.

Table below shows the level of service for roads classified according to the FFS and average travel speeds.

| Street class | I | II | III | IV |
| :---: | :---: | :---: | :---: | :---: |
| FFS | 89 to 72 kph | 72 to 56 kph | 56 to 48 kph | 56 to 40 kph |
| Typical FFS | 80 kph | 64 kph | 56 kph | 48 kph |
| LOS | Average travel speed $(\mathrm{kph})$ |  |  |  |
| A | $>68$ | $>56$ | $>48$ | $>40$ |
| B | $>55-68$ | $>45-56$ | $>39-48$ | $>31-40$ |
| C | $>43-55$ | $>35-45$ | $>29-39$ | $>21-31$ |
| D | $>34-43$ | $>27-35$ | $>23-29$ | $>14-21$ |
| E | $>26-34$ | $>21-27$ | $>16-23$ | $>11-14$ |
| F | $\leq 26$ | $\leq 21$ | $\leq 16$ | $\leq 11$ |

Table 4: Level of service (LOS) according to free flow traffic Street class

The road is considered class IV because the value of 45 kph for the FFS falls within the normal range ( 56 to 40 kph ) for a class IV arterial road, the average vehicle speed is 11 kph , therefore the LOS of the street is F . Level of service $F$ is most congested.

\[

\]

Flow rate $=3600$ /headway $4346=3600 /$ headway
Headway $=0.8 \mathrm{~s} / \mathrm{veh}$

Density $=1000$
spacing (m/veh)

```
395 = 1000
    Spacing
Spacing = 3m/veh
```

## CONCLUSION

1. The traffic volume ( $\mathrm{PCE} / \mathrm{hr}$ ) was found to be about $170 \%$ more than the hourly capacity (PCE/hr) for the road width description.
2. The congestion of vehicle along Keffi-Mararaba (Karu) Road at Mararaba Pedestrian bridge axis was found to be extremely high with LOS of class F.
3. Very low flow variation was recorded due to the PHF being high.

The following recommendations have been made:

1. There should be an expansion of the road to 4 lane, and other features like bicycle path (fitted for even the disabled), green space, walkway and others need to be provided to factor in sustainability requirements for the road. Tramways could also be additional traffic damners through the area.
2. There should be installation of state of the art traffic light and other furniture, to regulate the flow of traffic and the general service of the road.
3. There should be proper and timely maintenance plan of the road pavement and other features to improve serviceability.
4. They should be a taskforce teams set aside to file and arrest people selling directly on the pavement (shoulders) of the road. Hawking should be discouraged by constructing stalls at strategic locations and letting them out to the street hawkers.
